## 2.6 CIRCUIT DESCRIPTION

### 2.6.1 Outline

The NXR-5700 is a VHF repeater operating in the 136~174MHz frequency range. Transmit RF power range is 0.5W to 25W adjustable. Receiver's frontend BPFs are electrically adjusted in the factory.

### 2.6.2 Transmitter unit

The transmitter unit (XC1-065 A/3) consists of the following circuit.

- (1) 10MHz Internal frequency reference signal circuit
- (2) Internal/external reference signal circuit
- (3) Internal frequency reference 19.2MHz PLL circuit
- (4) Transmitter Modulation 16.8MHz PLL circuit
- (5) Transmitter main PLL circuit
- (6) Driver amplifier circuit
- (7) Modulation level adjustment circuit
- (8) AVR circuit
- (9) Other circuits

#### 2.6.2.1 10MHz internal frequency reference signal circuit

The internal frequency reference is generated by the 20MHz VCTCXO of X601. Oscillation frequency is adjusted by IC605, IC607 and IC608. If even one of X601, IC607 or IC608 is replaced, VCTCXO's frequency must be adjusted again.

After the 20MHz frequency reference signal is amplified by IC604, it is divided by IC602. 10MHz signal is distributed to TX unit. In addition, this 10MHz signal can be distributed to "REF OUT" terminal.

The 10MHz internal frequency reference signal circuit consists of IC602, IC604, IC605, IC607, IC608, D605, D606 and X601.

Fig.1 Internal reference circuit

#### 2.6.2.2 Internal/external reference signal circuit

The internal/external reference circuit automatically switches signals used as reference signals among the 10MHz internal reference signal, the 10MHz external reference signal and internal 10MHz OCXO (optional) unit.

If no OCXO unit is installed, and there is no external reference signal, the 10MHz internal reference signal is selected as the reference signal. This reference signal is fed to "REF OUT" terminal.

If the OCXO unit is installed and there is no external reference signal, the 10MHz OCXO unit is selected as the reference signal. This reference signal is fed to "REF OUT" terminal.

If an external reference signal (at CN502/ 10MHz/ 0~+10dBm) is input, the external reference signal is selected as the reference signal irrespective of the 10MHz internal reference signal or OCXO unit. This reference signal is fed to "REF OUT" terminal.

"REF OUT" terminal is CN601. The output level is more than + 5dBm ( $Z_{out} = 50\Omega$ ).

If the repeater is operating with NXR-x00 series for trunking mode, if there is no external reference signal and the OCXO unit is not installed, Q605, Q606, Q609, IC603 and IC606 are not activated. Therefore, there is no output of the reference signal from the "REF OUT" terminal.

The input impedance of external reference circuit is controlled by Q514. If "REF\_TERM" signal is high, the input impedance is low (approx. 50ohm). "REF\_TERM" signal is low, the input impedance is high (more than 1kohm).

The internal/external reference circuit consists of D501, D502, D503, D504, D507, D508, D509, D510, D511, D601, D602, D603, D604, D607, D608, D609, D610, D611, D612, D613, D614, D615, Q502, Q503, Q504, Q505, Q506, Q507, Q508, Q509, Q510, Q511, Q512, Q513, Q514, Q515, Q601, Q602, Q603, Q604, Q605, Q606, Q607, Q608, Q609, Q610, Q611, IC501, IC502, IC503, IC504, IC505, IC601, IC603 and IC606.

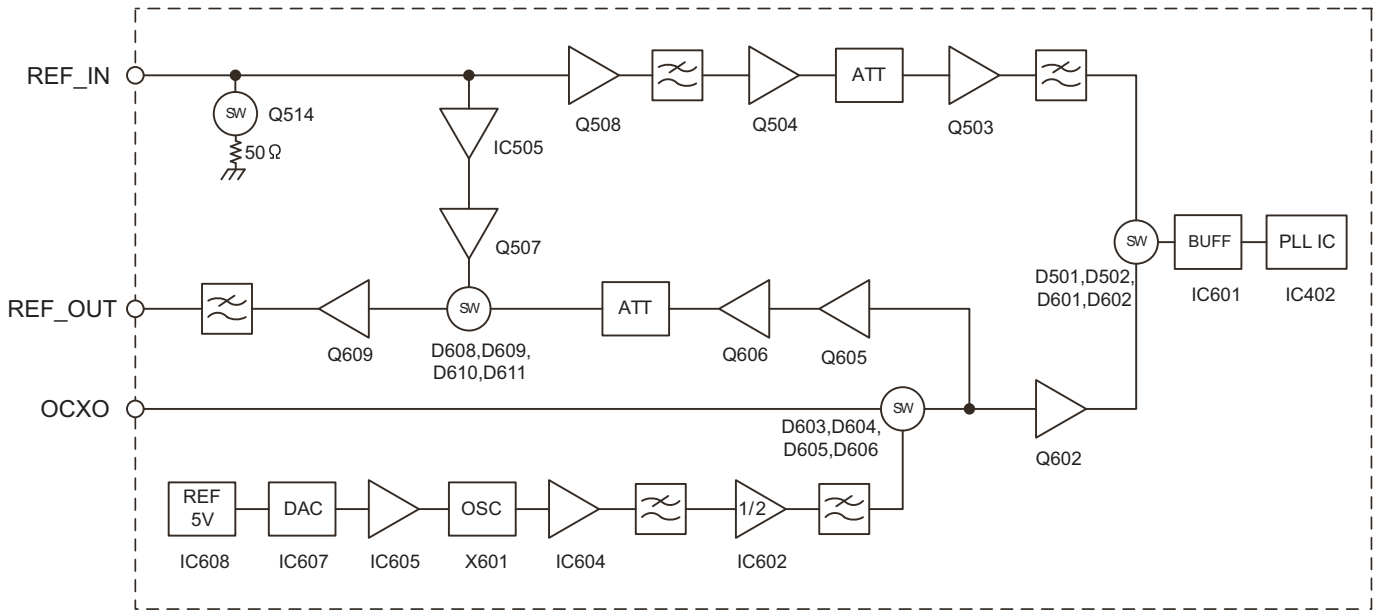

Fig.2 Internal/external reference circuit

### 2.6.2.3 Internal frequency reference 19.2MHz PLL circuit

The internal frequency reference 19.2MHz PLL circuit produces a reference frequency signal for the transmitter modulation 16.8MHz PLL circuit, the Receiver unit (XC1-066) Receiver PLL circuit and the Control Unit (XC1-064) PLL circuit for ASIC and DSP clock.

This circuit consists of Q402, Q403, Q404, Q405, Q406, Q407, Q408, Q409, Q410, Q411, X401, IC401 and IC402.

The internal or external 10MHz reference signal is amplified by IC601 and is fed to IC402 as a PLL reference signal.

VCXO of X401 generates 19.2MHz reference signal. The signal enters buffer amp Q403. Then it is amplified by Q404 to feed PLL IC of IC402. Also, the signal is amplified by Q402 to feed modulation PLL IC of IC301. Q410 amplifies the signal and feed the signal to receiver unit (XC1-066) from CN404. Q411 amplifies the signal and feed the signal to control unit (XC1-064) from CN405.

PLL IC of IC402 compares the phase between the 19.2MHz signal and the reference 10MHz signal. The phase error will be filtered as a DC signal and the DC signal controls the frequency of X401.

The controlled DC voltage is fed to IC401 operational amplifier, and the output signal (REF\_CV) is monitored by AD converter IC of IC804.

PLL's lock and unlock state is monitored by Q408 and Q409 as a signal name "REF\_UL".

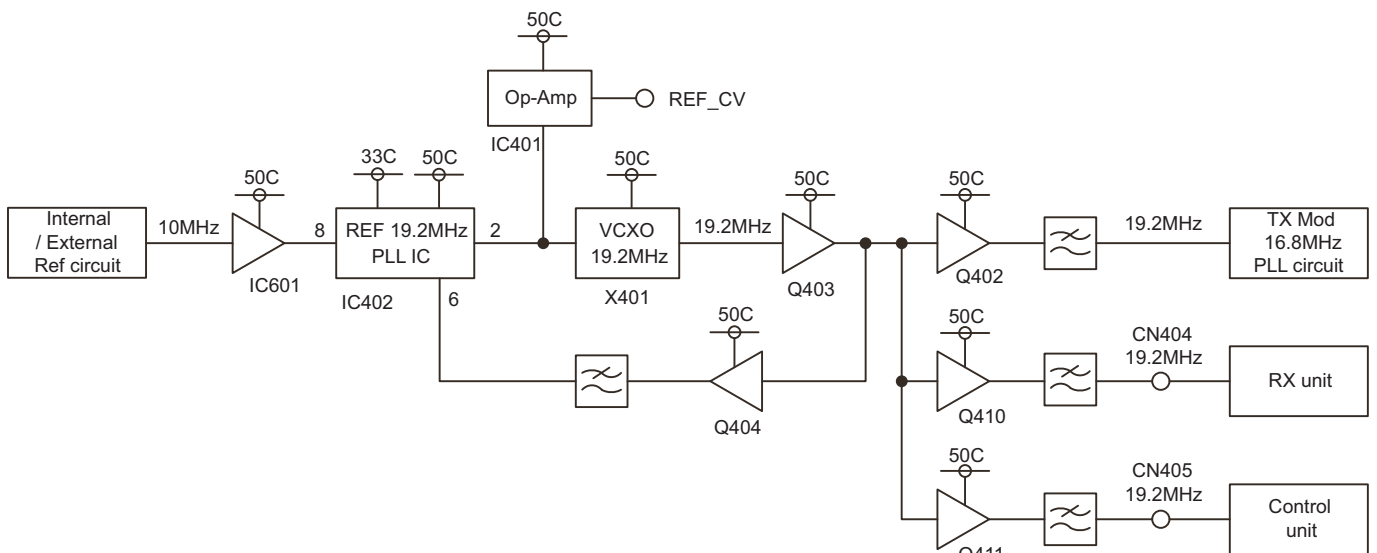

Fig.3 Internal frequency reference 19.2MHz PLL circuit

### 2.6.2.4 Transmitter modulation 16.8MHz PLL circuit

The transmitter modulation 16.8MHz PLL circuit produces the reference frequency signal for the Transmitter main PLL.

The circuit consists of Q301, Q302, Q303, Q304, Q305, X301, IC301, IC302 and IC303.

19.2MHz reference signal is amplified by Q402 and is fed to IC301 as a PLL reference signal.

VCXO of X301 generates 16.8MHz signal. The signal enters buffer amp Q305. Then it is amplified by Q304 to feed PLL IC of IC301. Also, the signal is fed to TX main PLL of IC104.

PLL IC of IC301 compares the phase between the 16.8MHz signal and the reference 19.2MHz signal. The phase error will be filtered as a DC signal and the DC signal controls the frequency of X301.

The modulation 16.8MHz PLL's loop bandwidth is very small (less than 5Hz). The modulation signal is added by IC302 to phase error filter output.

The controlled DC voltage is fed to IC303 operational amplifier from C317 and C320, and the output signal (MOD\_CV) is monitored by AD converter IC of IC804.

PLL's lock and unlock state is monitored by Q301 and Q302 as a signal name "MOD\_UL".

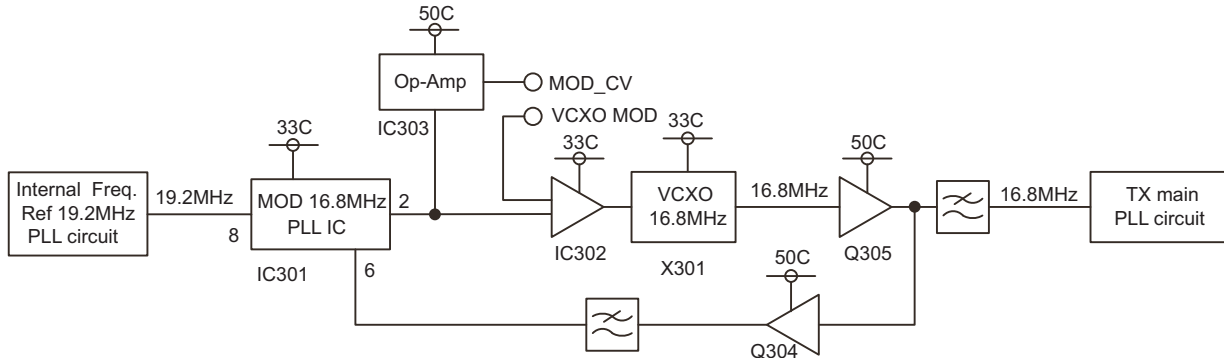

Fig.4 Transmitter Modulation 16.8MHz PLL circuit

### 2.6.2.5 Transmitter main PLL circuit

The transmitter main PLL circuit consists of the VCO (D103, D104, D105, D106, D107, D108, D109, D110, D111, D112, D113, Q101, Q102, Q105, Q106, Q107, Q108, Q109, IC101, IC102 and IC103) and PLL (Q103, Q110 and IC104). They produce the transmitter frequency signal.

If VCO\_A/B signal is high, Q105 is activated and the VCO Q107 produces transmitter frequencies from 136.000MHz to 154.995MHz.

If VCO\_A/B signal is low, Q106 is activated and the VCO Q108 produces transmitter frequencies from 155.000MHz to 174.000MHz. VCO oscillation frequency is controlled by TXASSIST signal mainly. The DC signal of TXASSIST is proportional to TX frequency.

The signal produced by the VCO (Q107 or Q108) is amplified by Q109. The signal is divided to PLL multiplier amplifier and driver amplifiers by a power divider circuit (L135, L136, C192 and R181).

PLL multiplier amplifier Q110 is multiply the VCO signal and feed the signal to IC104.

PLL IC of IC104 compares the phase between the multiplying of VCO signal and the reference 16.8MHz modulated signal. The phase error will be filtered as a DC signal and the DC signal controls the frequency of VCO.

PLL control voltage is constant value (2.9 to 3.1V) because the TXASSIST signal adjusts the VCO frequency roughly.

The controlled DC voltage is fed to IC103 operational amplifier, and the output signal (TX\_CV) is monitored by AD converter IC of control unit (XC1-064).

PLL's lock and unlock state is monitored by Q103 as a signal name "TX\_UL".

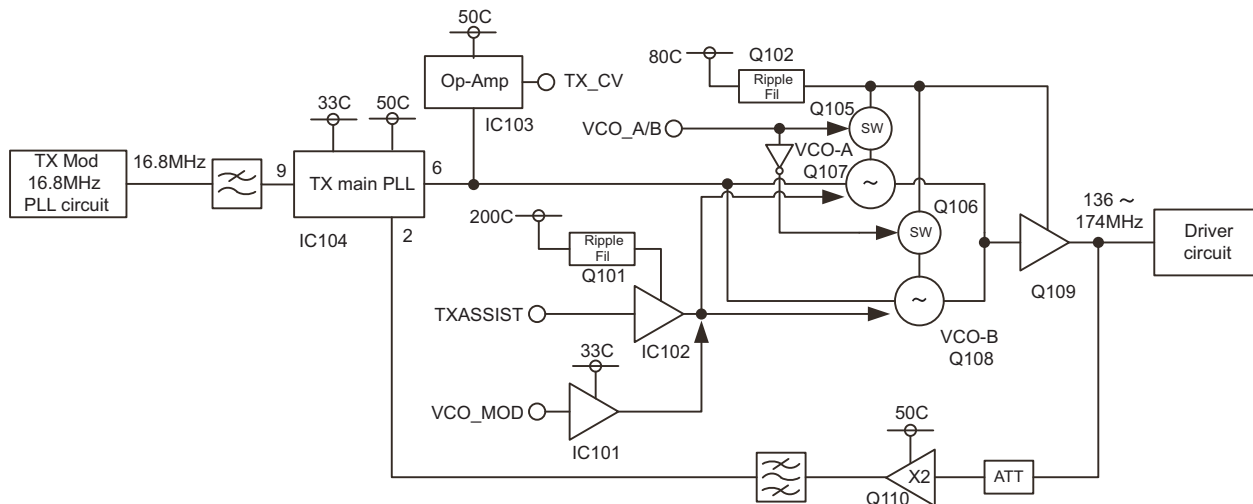

Fig.5 Transmitter main PLL circuit

### 2.6.2.6 Driver circuit

This circuit consists of RF amplifiers Q201, Q202 and Q204, switches Q203, Q207 and Q208, and operating amplifier IC201. DC switches Q207 and Q208 turn the power supply voltage of RF amplifiers Q201, Q202, and Q204 on and off. Q204 output power is controlled by IC201 and "DRV\_PWR" signal from IC801. Q204 output power is +16dBm. This output level is output from the driver output connector CN207 and connected to the Final Unit (XC3-015 A/5).

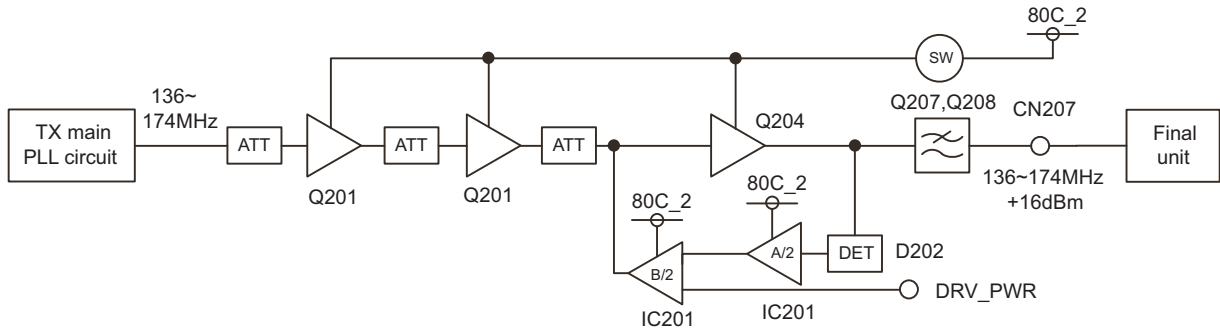

Fig.6 Driver circuit

### 2.6.2.7 Modulation level adjustment circuit

The modulation audio signal comes from the Control Unit (XC1-064) through CN722 pin1.

IC801 is an electronic volume control IC. Deviation of Transmitter main VCO and 16.8MHz modulation PLL is adjusted by IC801.

Subaudible modulation signal is fed to 16.8MHz modulation PLL. IC302 is an inverting amplifier of the modulating signal, and inverting amplifier of synthesizing the VCXO (X301) control voltage and modulating signal.

Audible modulation signal is fed to transmitter main VCO. IC101 is a non-inverting amplification of modulating signal. And it add to TX\_ASSIST voltage of IC102 output.

Fig.7 Modulation level adjustment circuit

#### 2.6.3.4 APC circuit

The automatic transmission power control (APC) circuit controls output power according to control voltage and stabilizes the transmitter output power at a pre-determined level.

DC voltage from the detector circuit is amplified by IC4,IC5.

The forward detection output and the reflection detection output offset by "PRT\_POW" are added by IC5.

Each detection voltage is sent to AD converter through IC400, and watched by MPU.

At the time of "Low Power", Q18 changes a gain of IC5 circuit.

When the amplitude is compressed in a process of the power limit adjustment, "RAMP" is supplied as "PWR\_LIM".

- Signaling number 1 is used for link test with voice.
- Signaling number 2 is used for TX modulation signal quality test. i.e, TX adjacent channel power, FSK error, Occupied bandwidth, Emission mask, etc.
- Signaling number 3 is used for TX deviation test. If the modulation mode is very narrow, the modulation frequency is 600Hz. If the modulation mode is narrow, the modulation frequency is 1200Hz.

#### 4.8 Confirmation and Alignment of Set-up to Prevent Receiver Desensitization

##### 4.8.1 Confirmation of Duplexer alignment

The duplexer allows the Repeater to simultaneously transmit and receive. To accomplish this, in the programmed receive frequency, the transmit frequency must be notched or suppressed by 75dB or more. Additionally, on the programmed transmit frequency, the receive frequency must be notched or suppressed by 75dB or more. The following figures are examples of Duplexer alignment using a spectrum analyzer.

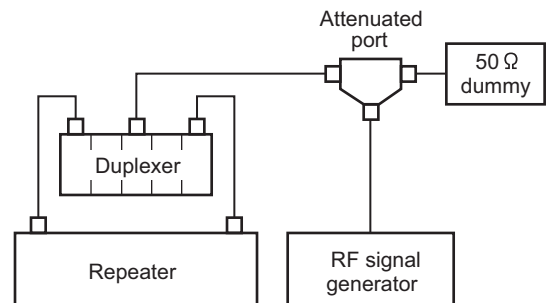

##### 4.8.2 Confirmation of Repeater Desensitization

The following figure is a Test set-up for Repeater Desensitization.

After this Test set-up is completed, confirm the Repeater Desensitization as mentioned below.

- (1) Disable the repeater mode.
- (2) Adjust the level of the RF generator until 12dB SINAD is reached.
- (3) Increase the output of the RF generator by 1dB. (This increases the SINAD.)
- (4) Enable the repeater mode.
- (5) Read the SINAD level. It should not drop below 12dB SINAD. If the SINAD is less than 12dB, check the tightness of the connectors and the tuning of duplexer.

#### 4.9 Adjustment for KXK-3(M3) (OCXO unit)

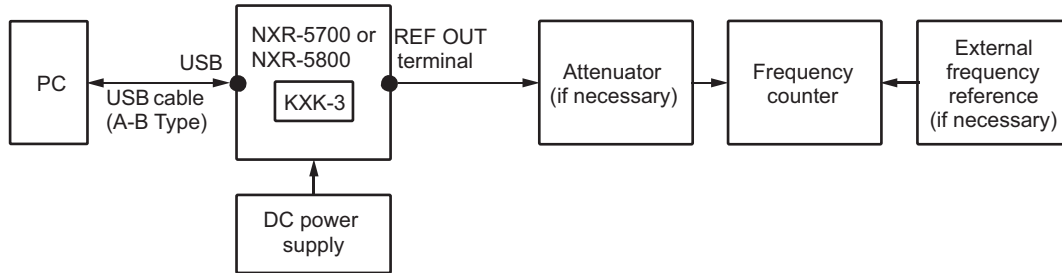

We recommend that the frequency adjustment be checked each time the radio is serviced, or at least once per two years. Maintenance should only be performed under normal temperatures.

##### ■Test Equipment Required for Alignment

Test Equipment	Major Specifications	
1. Frequency Counter	Frequency Range	Up to 50MHz
	Resolution	10 digits
	Reference Frequency Accuracy	Smaller than 0.0001ppm
	Input level	Up to 5Vpp

##### ■Adjustment Setup

The KXK-3(M3) OCXO unit must be mounted on the NXR-5700 repeater. Adjustment setup is shown as follows.

To adjust the KXK-3(M3) OCXO unit, some preparations are required.

- (1) The NXR-5700 with the KXK-3(M3) OCXO unit must be warmed up at least 72 hours before the adjustment is made. The environment temperature must be stable.
- (2) The frequency counter (or reference oscillator) must be warmed up as defined by the equipment manufacturer.

##### ■Adjustment

Item	Condition	Measurement			Adjustment			Specifications / Remarks
		Test-equipment	Unit	Terminal	Unit	Parts	Method	
1. Setting	1) Connect the DC power output to the rear panel DC terminal (13.6V). 2) Connect the "REF OUT" terminal to the frequency counter. 3) Warm-up the equipment and KXK-3(M3) properly. 4) Connect the front panel USB port to the PC USB port with a USB cable. 5) Activate the FPU to go to the test mode.							
2. OCXO frequency adjustment		f. counter	Rear	REF OUT		PC ADJ		±0.002ppm 9.99999998MHz~ 10.00000002MHz

##### Note:

Adjusted data is stored in the KXK-3 internal memory, therefore no re-adjustment is required when the adjusted KXK-3 is moved to another NXR-5700 or NXR-5800.

## 5.2 MPU(IC901) and DDR3 (IC791) Troubleshooting

Overview : The flowchart about troubleshooting of BGA package MPU (IC901) and DDR3 (IC791) .

This flowchart describe about "error display of e7" that is meant an error occurrence when the MPU (IC901) communicate to other MPU (IC200).

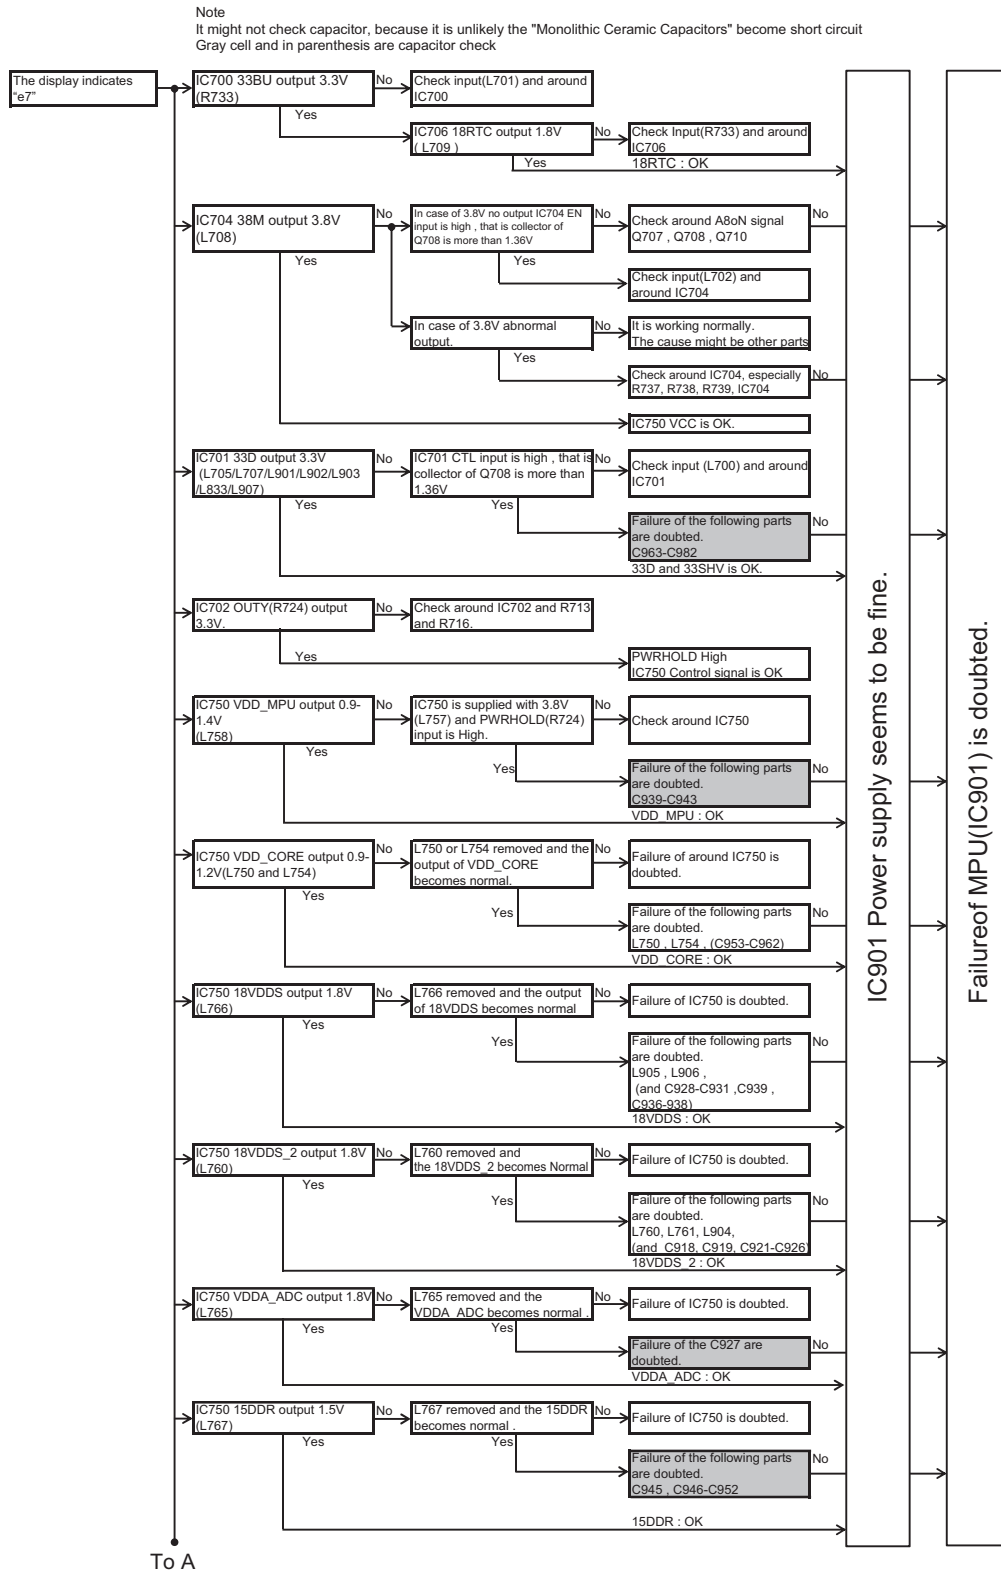

When repeater display error "e7" , we come to mind two main reason.

One reason is MPU makes trouble, the other is DDR3 makes trouble.

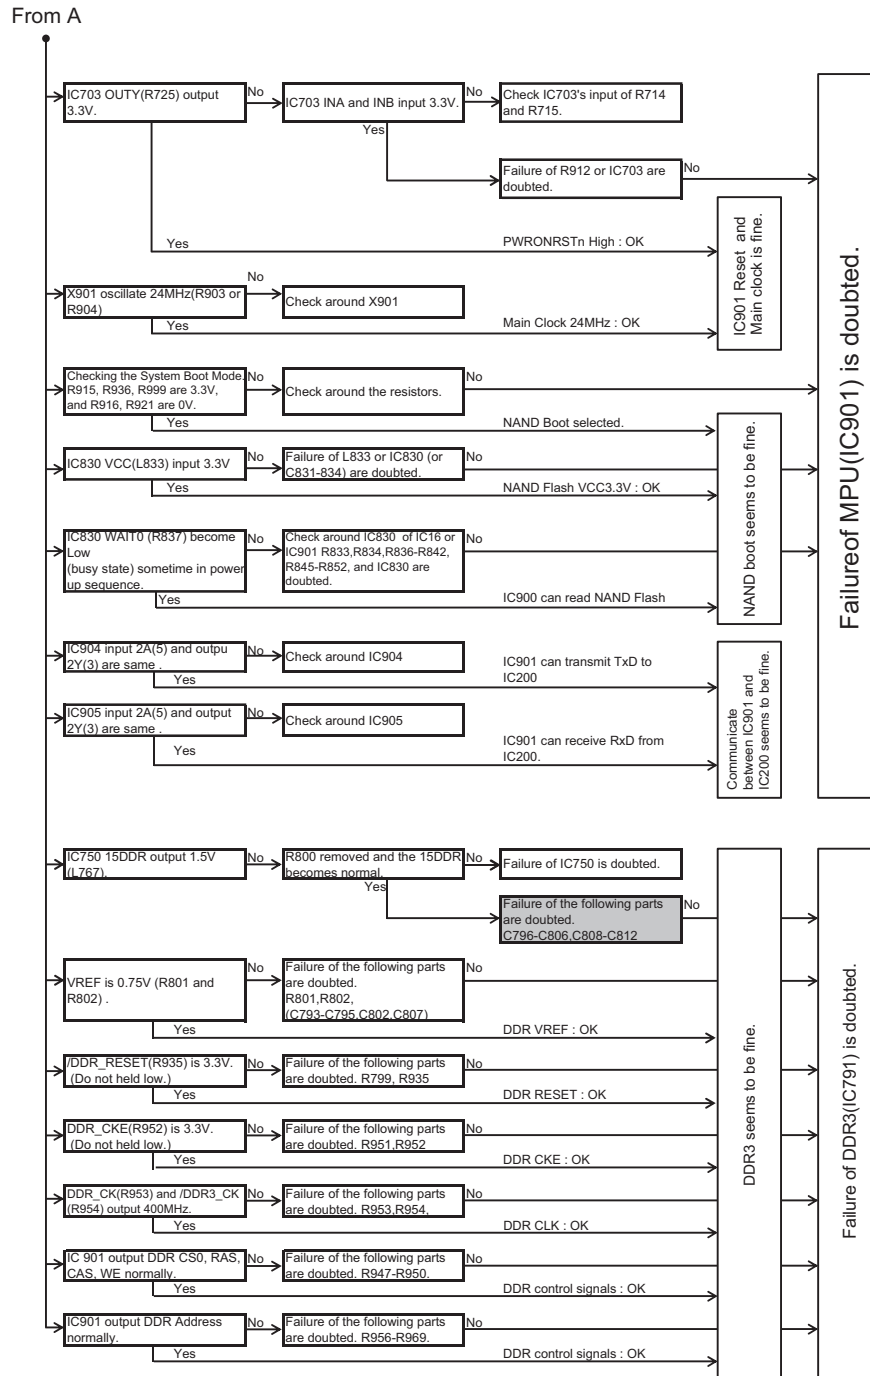

### 5.2.1 Outline for the process of MPU (901) and DDR3 (IC791) troubleshooting

## 5.2.2 Detail of MPU (901) and DDR3 (IC791) troubleshooting

### 5.3 If normal power is not obtained, please follow the steps below

- (1) Is the set current when the output becomes the upper limit appropriate for the output?  
When an excessive electric current is observed for the too little output, there is the example that the input to a module is not enough. So, is drive power enough?  
Try to readjust it if incompatible. And confirm a course reaching the module.
- (2) The output is the state of the upper limit, and observe gate voltage at that time.  
If around 5V that is the hardware-like upper limit appears, there is the abnormality on an output step or the output course.  
For example, it is power supply, module, coupling capacitor, LPF.  
When the power supply voltage at the module terminal abnormally descends, you should confirm each joint, main fuse, current detection resistance (R4).
- (3) When you cannot confirm enough gate voltage, there is the problem with a control block or a detection block.  
Can "PWR\_LIM" observe an appropriate value (limit adjustment up to around 3V)?  
The protector circuit malfunctions (in normal time Q2, Q451 OFF)?  
The reflection side detection circuit misdetects it (the R61 side of the coupler including non-connection)?  
Is the antenna switch replaced definitely?

■When a full power transmits and cannot lower the power.

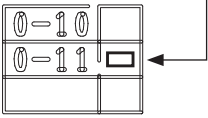

(1) Is the course of the forward side detection normal?

When the detection output is not provided though there is the real RF output, the APC is going to give max power.

(2) Confirm that you can turn down the "PWR\_LIM" output by power limit adjustment.

**Note:**

For the XC1-064, a UPC code and UPC barcode is not printed on the KENWOOD ESN Label. If necessary, cut the label at the cut-off line and attach only the serial number.

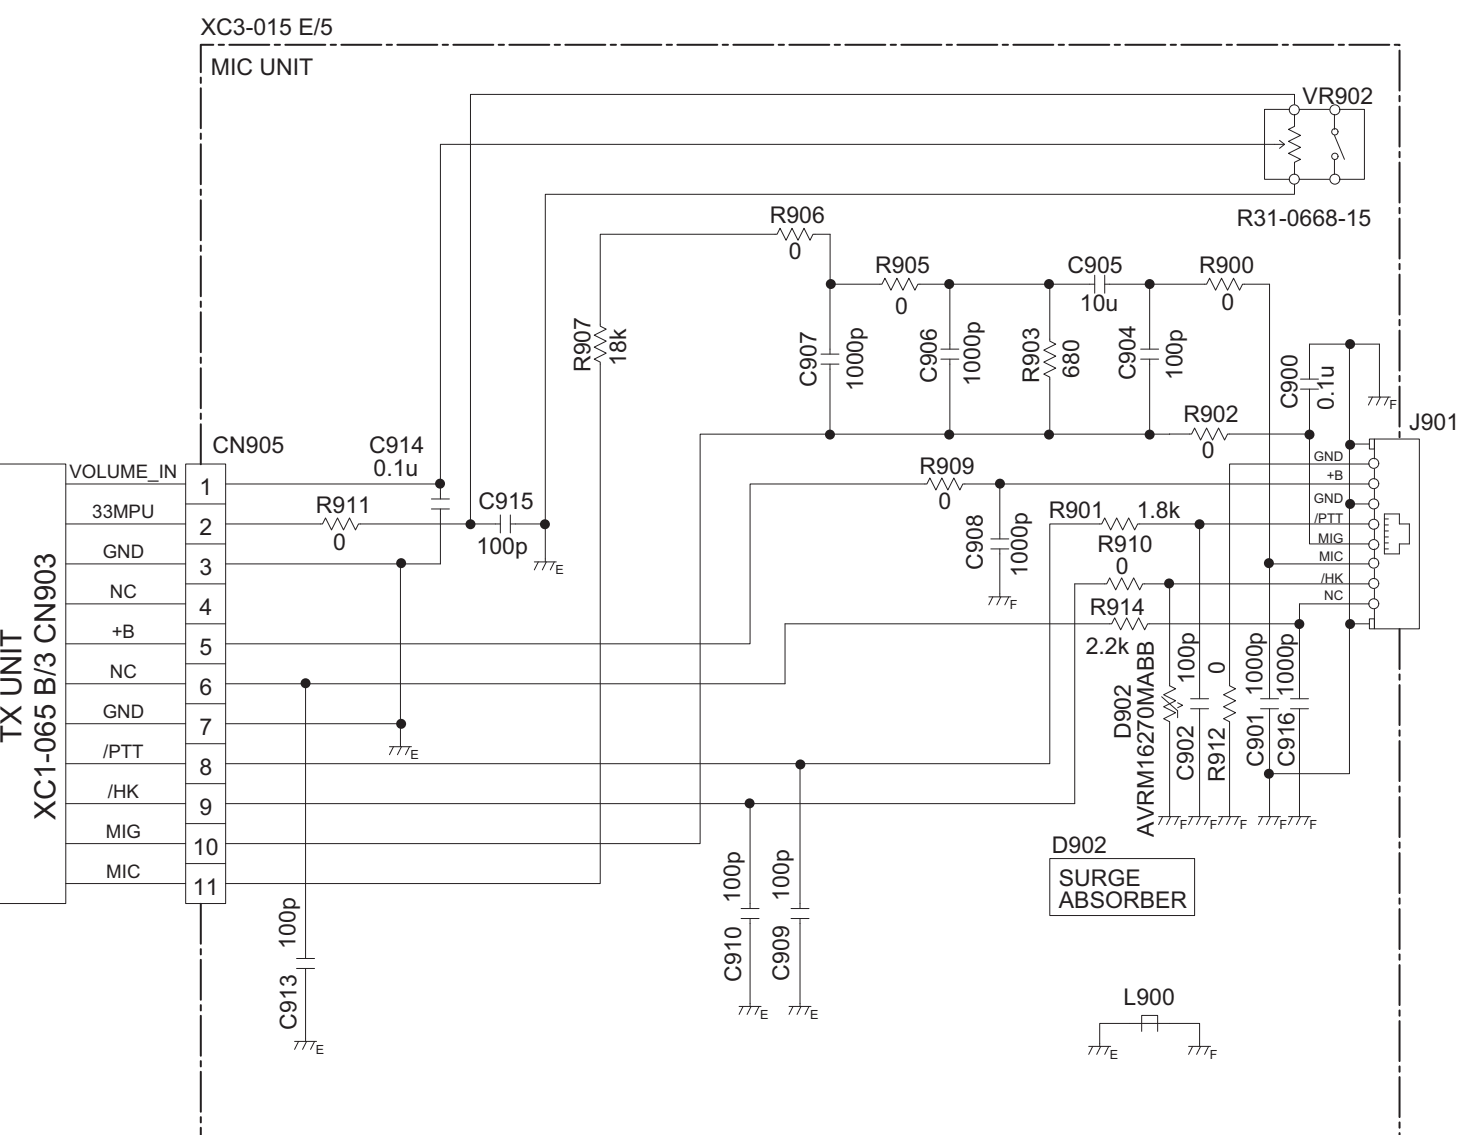

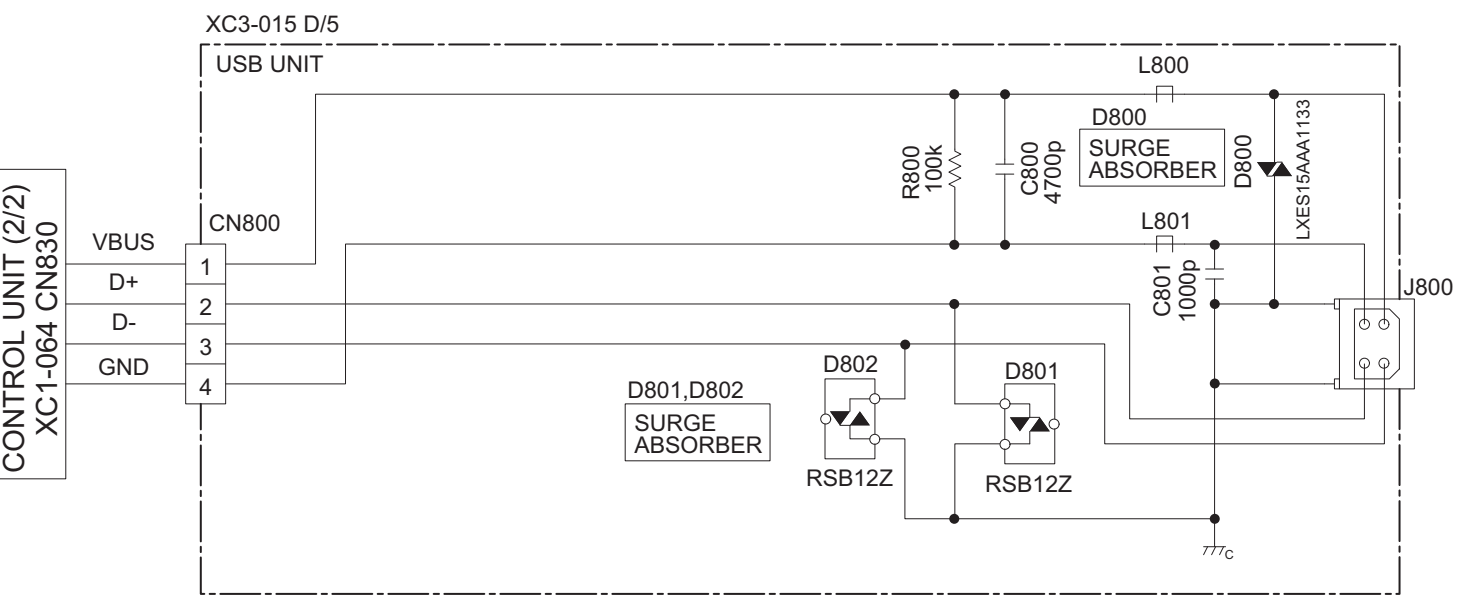

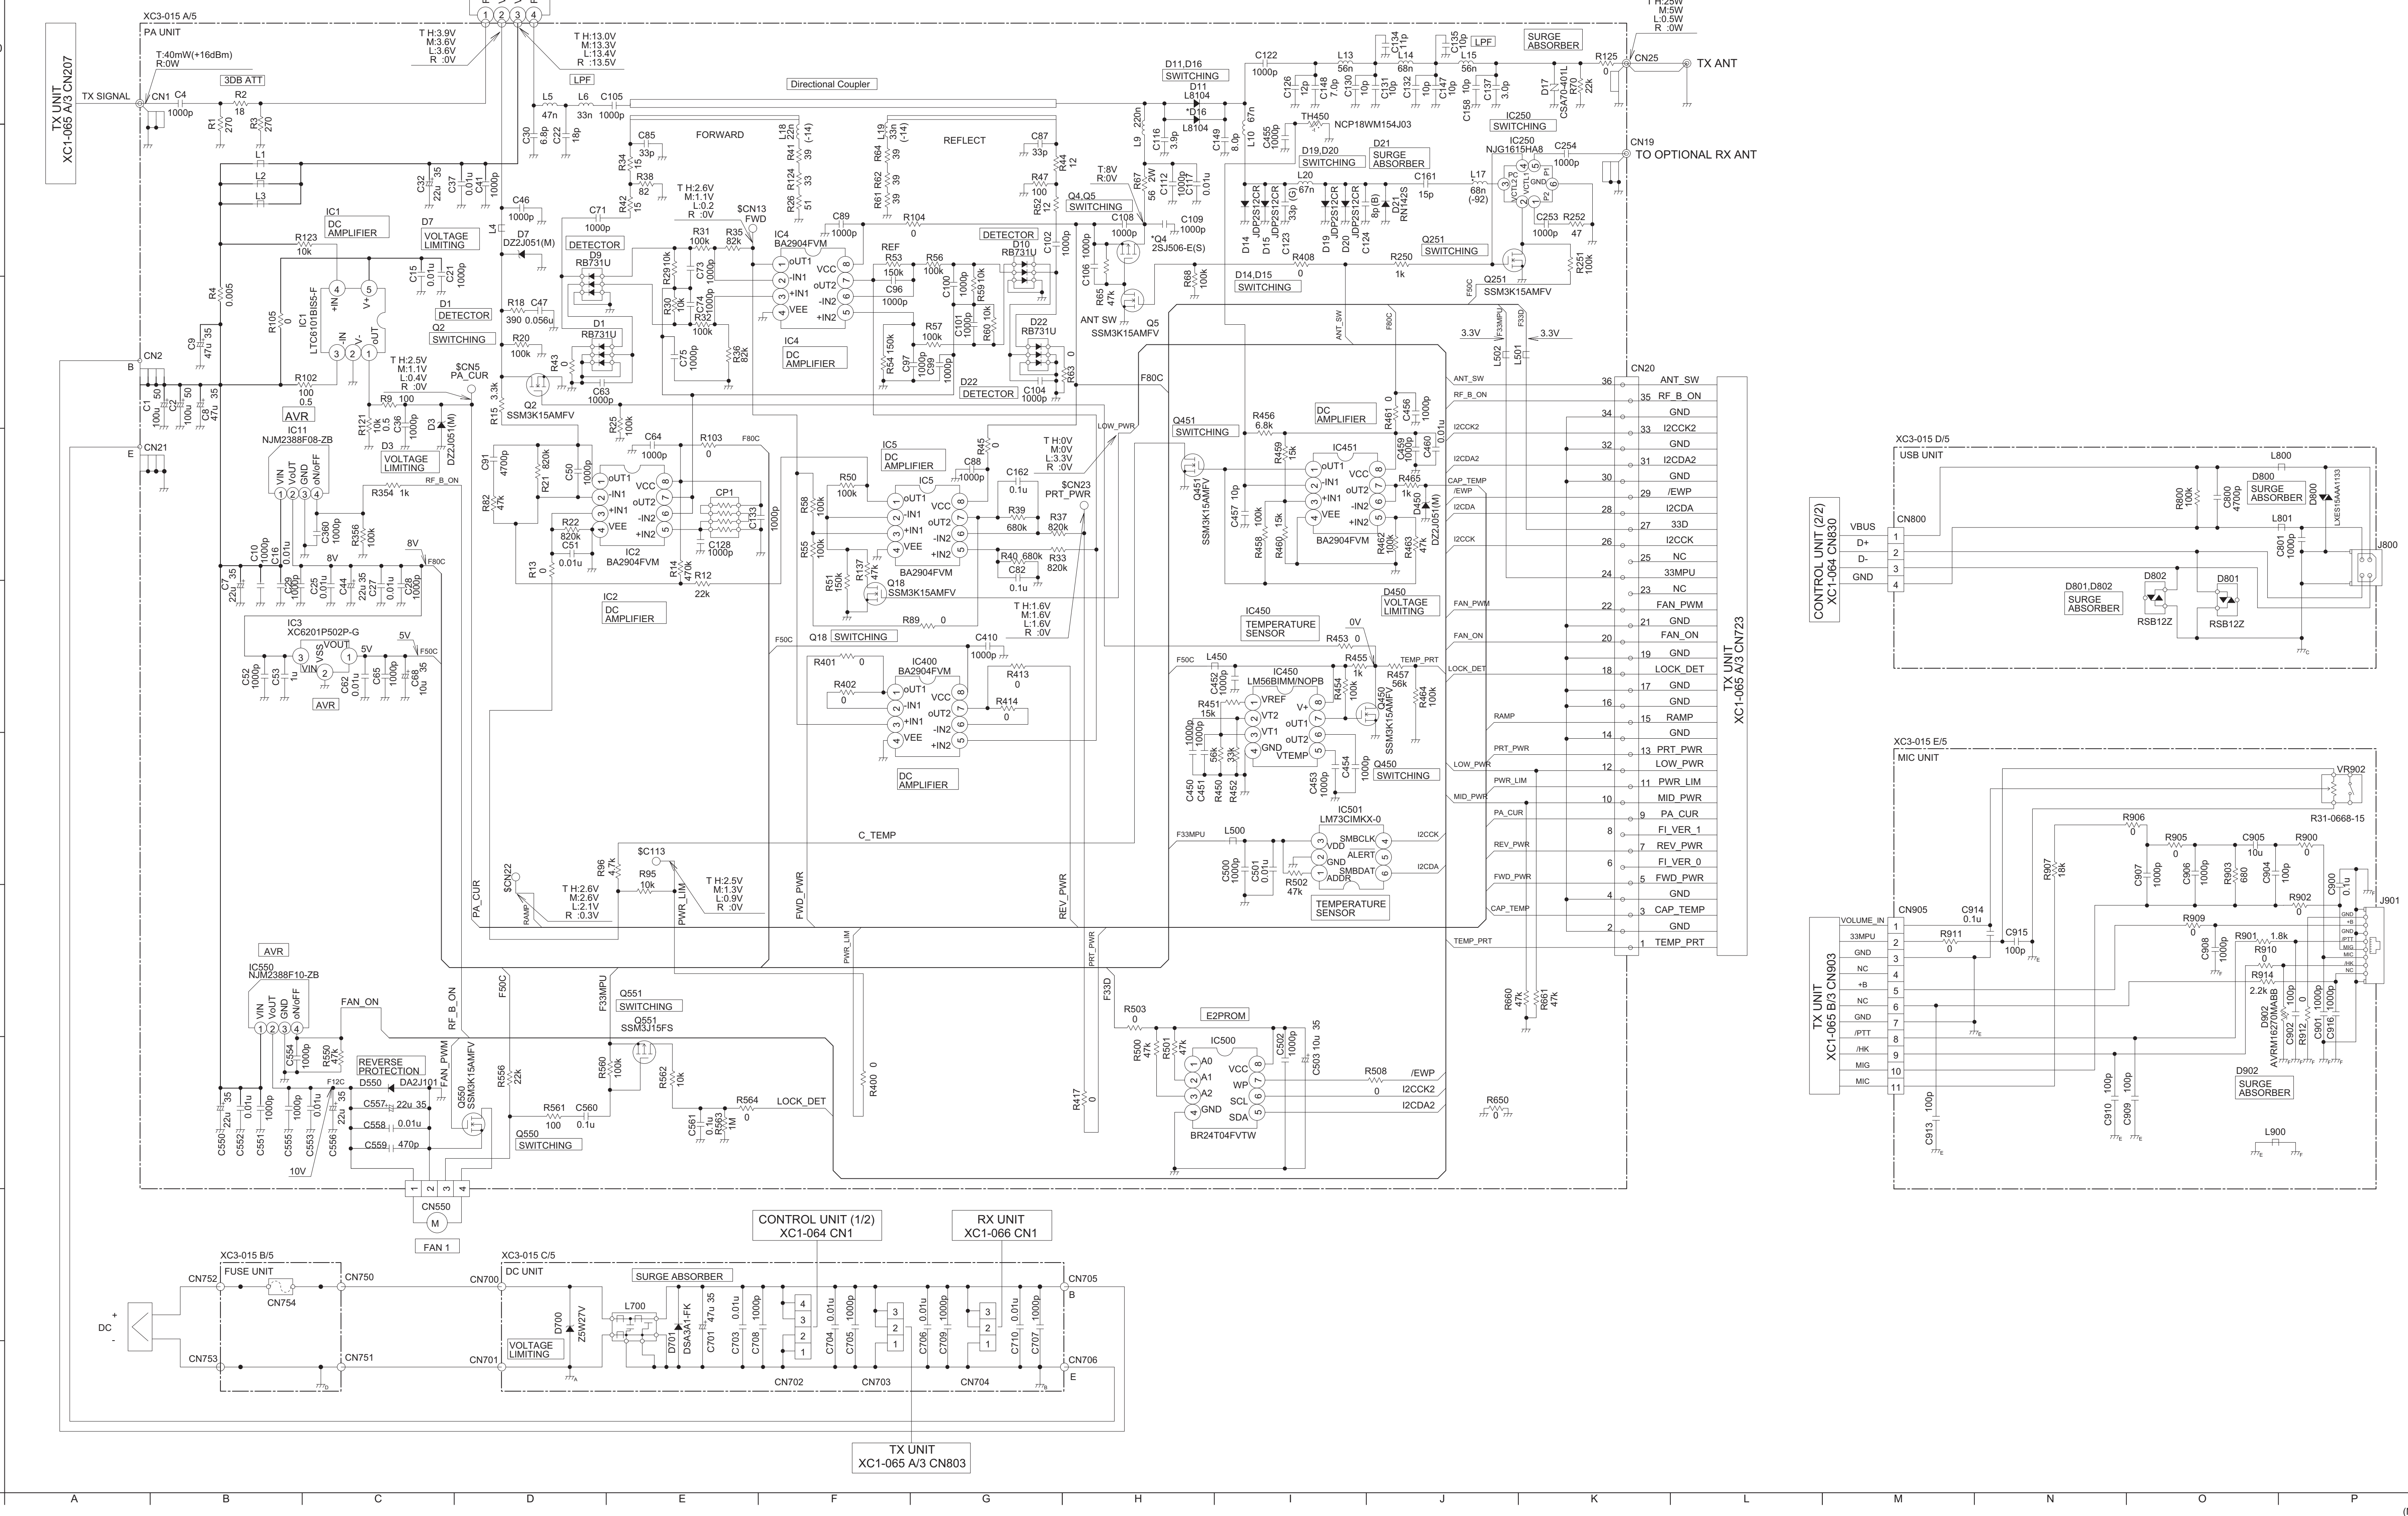

### 5.4.4 After Changing the PCB

- (1) After changing the printed circuit board, write the upto-date Firmware following the instructions in the "REALIGNMENT 4. Firmware Programming Mode".
- (2) Using the KPG-D2/D2N, select your desired item (Model Name and Frequency) from the Model > Product Information menu, then use Program > Write Data to the repeater to write the FPU data (PC Programming mode).  
When writing to the repeater, a Warning Message, corresponding to the item selected, appears. Click [OK] to continue writing the data.
- (3) Enter Program > Test mode, then adjust the various adjustment data (PC Test mode) as described in the "ADJUSTMENT".
- (4) For the XC1-064, attach the new labels corresponding to the new printed circuit board. (Refer to the images below for label placement.)
- (5) If necessary, write the FPU data used by the customer with the KPG-D2/D2N.

**Note:**

- When a new printed circuit board is used, the KENWOOD ESN changes, as does the Repeater Information display of the KPG-D2/D2N, but this does not have any effect on the operation of the transceiver.
- If changing to the original KENWOOD ESN and NXDN ESN, please contact our service center.
- Re-installing other parts from original unit to Service unit is not required after changing to Service unit.
